First-Principles Study of Er Location in Er-Si Systems with Oxygen Co-Dopants

R.H. PINK, JUNHO JEONG, DIP N. MAHATO, M.B. HUANG, T.P. DAS¹, SUNY Albany, R.H. SCHEICHER, MTU Houghton, SITARAM BYAHUT, Tribhuvan University, Kathmandu, Nepal — Using the Hartree-Fock cluster procedure, we are investigating possible models for the Er\(^{3+}\) ion in silicon with oxygen co-dopants[1]. We are examining first the Hi (hexagonal interstitial) site with six O atoms in the intrabond regions of the six Si-Si bonds for this center[2], allowing for relaxation in positions of the O and Si atoms. The aim of this study is to see if the presence of the O atoms is indeed able to change the situation of a maximum in the potential surface for Er\(^{3+}\) found from our recent investigations of the Er-Si system without co-dopants[1]. Results for the Er\(^{3+}\) potential curve for the Hi center and the geometries of the Si and O atoms will be presented.
