Ferromagnetism in Melt-spun Gd$_{0.946}$Fe$_{0.054}$

PAUL SHAND, NICHOLAS JENSEN, JUSTIN BOHNET, University of Northern Iowa, JARED GOERTZEN, JEFFREY SHIELD, University of Nebraska-Lincoln, DAVID SCHMITTER, Providence College, GEOFFREY SHELBURNE, DIANDRA LESLIE-PELECKY, University of Nebraska-Lincoln — The ac susceptibility and dc magnetization at various temperatures have been measured for a melt-spun Gd$_{0.946}$Fe$_{0.054}$ alloy. The grain size was $\approx 100$ nm. A sharp paramagnetic-to-ferromagnetic transition was observed at a temperature close to that of pure Gd. Effective critical exponents and the critical temperature $T_C$ were extracted by using modified Arrott plots and Kouvel-Fisher analysis. The values obtained were $\beta_{\text{eff}} = 0.398 \pm 0.004$, $\gamma_{\text{eff}} = 1.24 \pm 0.02$, $\delta_{\text{eff}} = 3.83 \pm 0.05$, and $T_C = 290.25 \pm 0.17$ K. These exponent values do not satisfy the Widom scaling relation $\beta\delta = (\beta + \gamma)$. The $\beta_{\text{eff}}$ and $\gamma_{\text{eff}}$ values for ms-Gd$_{0.946}$Fe$_{0.054}$ are similar to those obtained for pure Gd in the same temperature interval around $T_C$. This is in consonance with x-ray microanalysis measurements indicating that the grains are nearly pure Gd. The lower-than-expected value of $\delta_{\text{eff}} g$ may be due to the effect of increased anisotropy due to the presence of Fe in the grain-boundary regions.
