Abstract for an Invited Paper  
for the MAR08 Meeting of  
the American Physical Society

**Bi-layer  $^3\text{He}$ : a simple two dimensional heavy fermion system with quantum criticality<sup>1</sup>**

JOHN SAUNDERS, Royal Holloway University of London

Two dimensional helium films provide simple model systems for the investigation of quantum phase transitions in two dimensions. Monolayer  $^3\text{He}$  adsorbed on graphite, with various pre-platings, behaves as a two dimensional Mott-Hubbard system, complete with a density driven “metal-insulator” transition [1, 2] into what appears to be a gapless spin-liquid. In two dimensions the corrections to the temperature dependence of the fluid heat capacity, beyond the term linear in  $T$ , are anomalous and attributed to quasi-1D scattering [3]. On the other hand, bi-layer  $^3\text{He}$  films adsorbed on the surface of graphite show evidence of two-band heavy-fermion behavior and quantum criticality [4, 5]. The relevant control parameter is the total density of the  $^3\text{He}$  film. The  $^3\text{He}$  bilayer system can be driven toward a quantum critical point (QCP) at which the effective mass appears to diverge, the effective inter-band hybridization vanishes, and a local moment state appears. A theoretical model in terms of a “Kondo breakdown selective Mott transition” has recently been suggested [6]. \* In collaboration with: A Casey, M Neumann, J Nyeki, B Cowan.
