Eskildsen, Dept. of Physics, U. of Notre Dame, Notre Dame, IL, USA, J. S. White, E. M. Forgan, School of Phys. and Astro., U. of Birmingham, Birmingham, UK, Z. Fisk, Dept. Phys. & Astro., UC Irvine, Irvine, CA, USA, R. Movshovich, E. D. Bauer, J. L. Sarrao, MPA-10, LANL, Los Alamos, NM, USA, C. Petrovic, Cond. Matt. Phys., BNL, Upton, NY 11973, USA — We report on the magnetic field ($\mathbf{H}$) dependence of the form factor $|F|^2$ of the vortex lattice (VL) in CeCoIn\textsubscript{5} obtained by small angle neutron scattering for $\mathbf{H}$ applied along the crystallographic c-axis. Superconductivity (SC) in CeCoIn\textsubscript{5} has several unconventional aspects to it: The $d$-wave SC is in competition with antiferromagnetic order, as suggested by the presence of a magnetic QCP located at the upper critical field $H_{c2}$ determined by the Pauli effect. At both 50 and 500 mK we observe an $H$-independent $|F|^2$ up to 2 T. With further increasing $H$, $|F|^2$ continues to increase all the way up to $H_{c2}$. This finding is in contrast to that normally observed in type-II SC's, where $|F|^2$ decreases with increasing $H$. It suggests a departure from the Abrikosov-Ginzburg-Landau paradigm, where the properties of the vortex state can be described by the coherence length $\xi$, and the penetration depth $\lambda$.
