Our recent water adsorption experiments suggest that the entropy of surface water is lower than those of bulk water and ice implying restricted motion of the water on the surface. We have studied dynamics of water on nanoparticles of two oxides, TiO$_2$ and SnO$_2$ by inelastic neutron scattering. Vibrational density of states for surface phonons of water confined by oxide surfaces has been calculated. Heat capacity of confined water has been measured by adiabatic calorimetry and compared with values derived from the vibrational density of states.
