MACIEL, IF-UFPR, Curitiba, Brazil, J.A. SOUZA, CCNH-UFABC, Santo André, Brazil, J.A. ALONSO, M.J. MARTINEZ, CSIC-ICMM-Cantoblanco, E28049 Madrid, Spain, G.M. AZEVEDO, LNLS, Campinas, Brazil — EXAFS measurements from 20 K to 300K were used to investigate the local structure of multiferroic RMn$_2$O$_5$ (R = Bi, Pr, Gd, TM TC 40K) in transmission mode at the Mn K- and R L$_3$- edges in the XAFS2LNLS beamline and analyzed using the IFEFFIT and FEFF codes. For BiMn$_2$O$_5$, Mn K-edge reveals very small temperature dependence of the Debye-Waller factor (DWF) and an Einstein temperature (ET) from Mn-O bonds of 675\(^\pm\)22 K, suggesting that MnO polyhedra are rigid. We find structural distortions in the first coordination shell at the Bi L$_3$-edge associated to vibrational anomalies in the Bi-O bonds. The quantitative analysis relates the origin of such distortions to two very distinct values of DWT and ET (294\(^\pm\)7K and 462\(^\pm\)28K) for these bonds on first shell. Similar behavior is observed for PrMn$_2$O$_5$, and GdMn$_2$O$_5$.
