Anomally high conductivity in bromine-intercalated graphite\textsuperscript{1}

A.F. HEBARD, S. TONGAY, J. HWANG, D.B. TANNER, D. MASLOV, University of Florida — We have found that when graphite is intercalated with bromine, the \(ab\)-plane (\(c\)-axis) conductivity sharply increases (decreases). Characterization of the Br intercalated samples by exposure time, weight uptake, sputter Auger spectroscopy and X-ray diffraction show a Br concentration that is uniformly distributed within a graphite host having an expanded interplanar spacing \(d_c\). The \(ab\)-plane conductivity is enhanced by several orders of magnitude in the temperature range from 300 K down to 1.7 K and shows no sign of saturation with increasing Br concentration. Hall measurements confirm a pronounced increase in the density of negative carriers consistent with an increased optical reflectivity (below 3000 cm\(^{-1}\)). The inferred plasma frequencies and extrapolated dc conductivities are consistent with the transport measurements. The diamagnetic susceptibility decreases with increasing Br concentration and follows a temperature dependence from which a Fermi energy that increases with increasing Br concentration is extracted. By increasing \(d_c\), the \(ab\)-plane conductivity of Br intercalated graphite begins to resemble the additive contributions of parallel connected doped graphene sheets and thus has implications for carbon based electronics.
