Berry phase and the role of trigonal warping in graphene systems

IVAN STANIC, KARYN LE HUR, Yale University — In general Dirac fermions exhibit a Berry phase of π whereas non-relativistic free-like particles have a Berry phase of 2π . The two cases have been reported, both theoretically and experimentally, in single-layer and bi-layer graphene respectively. On the other hand, if one considers, for example, bi-layer graphene in more detail, its band structure shows both the Dirac-type, coming from the trigonal warping, and the parabolic, non-relativistic aspect in different energy regimes. This gives an unprecedented opportunity to investigate the **crossover between non-relativistic and Dirac fermions in a Berry phase formulation**. Here, we propose a scattering type-experiment (reflecting the Berry phase) to demonstrate this crossover. We present our theoretical results on scattering cross-sections taking into account the trigonal warping term, which confirm the jump in the Berry phase from π to 2π as the energy of the incoming electrons is increased. This jump in the Berry phase can be understood from a general theorem relating the Berry phase and the band structure of a material.
