**Emergence of complex magnetism in three dimensional, yet quasi-layered, iron pnictides:  $\text{CaFe}_4\text{As}_3$** <sup>1</sup> ARTHUR J. FREEMAN, GIANCARLO TRIMARCHI, MERCOURI KANATZIDIS, Northwestern U., ILIYA TODOROV, DUCK-YOUNG CHUNG, Materials Science Division, ANL, Argonne IL 60439 — The class of iron pnictides has been the focus of much attention for the discovery of superconductivity in the layered compounds  $\text{LaOFeAs}$ ,  $\text{CaFe}_2\text{As}_2$ , and related ones; the phase diagrams of these pnictides remain still largely unexplored. Here, we report on the electronic and magnetic structure of the recently synthesized  $\text{CaFe}_4\text{As}_3$  compound. This material, as opposed to the layered  $\text{CaFe}_2\text{As}_2$ , shows FeAs slabs parallel to the  $b$ -direction and approximately perpendicular to each other, defining tunnels filled by the Ca atoms. No sign of superconductivity was found in this compound. Instead, the system shows a complex ferromagnetic state at low temperature. DFT calculations performed on the refined crystal structure using the highly precise FLAPW method<sup>2</sup> show a pronounced stabilization for the ferromagnetic state which is characterized by four distinct Fe sites with magnetic moments of between  $1 \mu_B$  and  $2 \mu_B$ . The influence of the local topology of the crystal structure on the the electronic and magnetic state is analyzed.
