Cyclotron Resonance at the Dirac Point PAUL CADDEN-ZIMANSKY, Columbia University/NHMFL, ERIK HENRIKSEN, Columbia University, ZHIGANG JIANG, Georgia Tech University, LI-CHUN TUNG, NHMFL, MOLLIE SCHWARTZ, Columbia University, YONG-JIE WANG, NHMFL, PHILIP KIM, Columbia University, HORST STORMER, Columbia University/Bell Labs — We present high field infrared spectroscopy data on the n = -1 → 0 and n = 0 → 1 Landau Level (LL) transitions in graphene. At high magnetic fields, up to 31 T, measurements of single layer graphene show large shifts in the transition energies, which are suggestive of a gap in the n = 0 LL. The magnitude of these shifts are strongly enhanced over the bare Zeeman splitting naively expected for a spin-split state. We compare the field dependence of the shifts with proposed degeneracy-breaking mechanisms at the Dirac point.
