ZHOU, Department of Physics, Michigan State University, Lansing, MI; G. M. LUKE, A. A. ACZEL, G. J. MACDOUGALL, Department of Physics and Astronomy, McMaster University, Hamilton, ON; P. W. STEPHENS, Department of Physics, SUNY at Stony Brook, Stony Brook, NY — $\text{V}_2\text{O}_3$, which has been the subject of investigations for well over 30 years, is a classic example of a Mott-Hubbard transition system. This first-order metal-insulator transition, near 160K, is accompanied by a rhombohedral-monoclinic structural as well as a paramagnetic-antiferromagnetic magnetic transition. We report on structural synchrotron x-ray characterization of $\text{V}_2\text{O}_3$ nanopowder (dia $\approx$ 10-50 nm) at NSLS, and magnetic characterization via muon spin relaxation at TRIUMF. We find that, just as in bulk $\text{V}_2\text{O}_3$, the structural and magnetic transitions are concurrent, and that in contrast to the abrupt and hysteretic transition witnessed in the bulk, in the nanopowder sample the transition occurs with phase separation over a broad temperature range.
