ABC Triblock Copolymer Vesicles with Mesh-like Morphology

WEI ZHAO, THOMAS RUSSELL, GREGORY GRASON, Department of Polymer Science and Engineering, University of Massachusetts, Amherst — Polymer vesicles can be made from poly(isoprene-*b*-styrene-*b*-2-vinylpyridene) (PI-*b*-PS-*b*-P2VP) triblock copolymer under the confinement of anodic aluminum oxide (AAO) membrane. It was found that these vesicles have well-defined, nanoscopic size and a microphase-separated hydrophobic core, comprised of PS and PI blocks. Vesicle formation was tracked using both transmission and scanning electron microscopy. A mesh-like morphology formed in the core at a well-defined composition of three blocks. Confinement played an important role in generating these vesicles with such an unusual morphology.
