Study of Phase Transitions in Barium Titanate - Liquid Crystal Nano-colloidal Suspensions

KRISHNA SIGDEL, GERMANO IANNACCIONE, Worcester Polytechnic Institute — A high-resolution ac-calorimetric study of the isotropic to nematic (I-N) and the nematic to smectic-A (N-SmA) phase transitions in nano-colloidal suspensions of Barium Titanate (BaTiO₃) in the liquid crystal (LC) octylycyanobiphenyl (8CB) as a function of BaTiO₃ concentration is reported. Heating and cooling scans were performed for all samples (0.1 - 1.4 wt% of BaTiO₃ and pure 8CB) over a wide temperature range well above and below the two transitions. Both the I-N and the N-SmA transitions evolve in character and have their transition temperatures shift lower as the wt% of BaTiO₃ increases. Increasing hysteresis with increasing concentration is also observed at the I-N transition between heating and cooling scans within the two-phase I+N coexistence region. These results will be contrasted with other LC colloidal dispersion systems.
