Near-field Optical Measurement using Nano-Prism Probes

TAEKYEONG KIM, BYUNG YANG LEE, KWANG HEO, SEUNGHUN HONG, Seoul National University, KI SEOK JEON, HYUNG MIN KIM, YUNG DOUG SUH, KRICT, DEOK SOO KIM, ZEE HWAN KIM, Korea University — Recently, a nano-prism (NP) structure has drawn attention as an optical nano-antenna due to its exotic optical properties, while it has been extremely difficult to prepare a probe terminated with a NP for near-field optical measurement. Herein, we report a method to mass-produce pristine NP-probes. Our fabrication process allowed us to prepare *NPs with sharp edge at the end of the probes*, which significantly enhanced the electric fields around the probes and made the NP-probes ideal for nano-optical applications. We performed the apertureless near-field scanning optical microscopy on gold nanoparticles using a NP-probe, revealing the field localization at the vertices of the NP. We also achieved high resolution topographic imaging on carbon nanotubes and successfully performed the tip-enhanced Raman spectroscopy (TERS) experiment on brilliant cresyl blue (BCB) molecules, revealing a significant field localization at the sharp edge of the NP. This method could be a major breakthrough and provide tremendous flexibility for near-field optical applications.
