stress response of silver nanoparticle film on a water subphase

KYUNGIL KIM, BRIAN LEAHY, University of Chicago, YELING DAI, University of California at San Diego, JANET SOLTAU, University of Vermont, OLEG SHPYRKO, University of California at San Diego, MATI MERON, BINHUA LIN, University of Chicago — We examine the stress response of a film composed of dodecanethiol-ligated silver nanoparticles and supported on a water subphase, using optical microscopy and synchrotron x-ray techniques (x-ray reflectivity and grazing incidence x-ray diffraction). We observe a monolayer-to-bilayer transition, which is followed by wrinkling and folding of the nanoparticle film. The results are quantitatively different from a similar film of gold nanoparticles, which undergoes a monolayer-to-trilayer transition and wrinkles with a longer wavelength. The silver film is also less covered in wrinkles and folds than the gold film at similar compressive strains, and the wrinkles quickly relax when compression is stopped.
