High-lying resonances in Ps-H scattering below the $H^- - e^+$ threshold

Z.-C. YAN, University of New Brunswick Fredericton, New Brunswick, Canada, YEW KAM HO, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, Taiwan — In this work, we carry out an investigation of high-lying $S$-wave resonances in Ps-H scattering below the $(H^- - e^+)$ threshold. The method of complex-coordinate-rotation [1] is used together with employing highly correlated wave functions containing all six inter-particle coordinates. Using such Hylleraas-type bases [2] up to 6412 terms, the energy positions and widths up to the $7S$ state in the Rydberg series converging to the $H^-$ threshold are calculated. The high-lying resonances from our present calculations are fitted to a quantum defect formula, and from which the energies of even higher members of the Rydberg series can be deduced. [1]. Y. K. Ho, *Phys. Rept.* 99, 1 (1983). [2]. Z.-C. Yan and G. W. F. Drake, *J. Phys. B* 30, 4723 (1997).
