Structural and electronic properties of single-crystal $\text{Fe}_{1-x}\text{Co}_x\text{As}$

K. KIRSHENBAUM, S. SAHA, N. BUTCH, T. DRYE, J. MAGILL, J. PAGLIONE, University of Maryland, College Park, Center for Nanophysics and Advanced Materials, P. ZAVALIJ, University of Maryland, College Park, Department of Chemistry and Biochemistry — Shortly after the discovery of the iron pnictide superconductors, it was found that cobalt substitution on the iron site in the 122 ternary systems AEFe_2As_2 (AE = alkali earth) suppresses the magnetic order of the parent compounds and induces superconductivity. While transition metal substitution in the intermetallic iron arsenide superconductors is one of the most studied aspects of these materials, there is little known about the effects of substitution on the related binary system FeAs. We present transport and magnetization measurements performed on single crystals of the cobalt-substituted system $\text{Fe}_{1-x}\text{Co}_x\text{As}$, and discuss the evolution of the phase diagram of this system.
