Scanning Gate Microscopy on a Quantum Hall Interferometer
FREDERICO MARTINS, BENOIT HACKENS, AUGUSTIN DUTU, VINCENT BAYOT, Universite Catholique de Louvain, Louvain-la-Neuve, Belgium, HERMANN SELLEIR, SERGE HUANT, Institut Neel, Grenoble, France, LUDOVIC DESPLANQUE, XAVIER WALLART, IEMN, Villeneuve d’Ascq, France, MARCO PALA, IMEP-LAHC, MINATEC, Grenoble, France — We perform scanning gate microscopy (SGM) experiments [1] at very low temperature (down to 100 mK) in the Quantum Hall regime on a mesoscopic quantum ring (QR) patterned in an InGaAs/InAlAs heterostructure. Close to integer filling factors $\nu=6, 8$ and $10$, the magnetoresistance of the QR is decorated with fast periodic oscillations, with a magnetic field period close to $AB/\nu$, where $AB$ is the Aharonov-Bohm period. We analyze the data in terms of electron tunneling between edge states trapped inside the QR and those transmitted through the QR openings [2]. SGM images reveal that the tip-induced perturbation of the electron confining potential gives rise to a rich pattern of narrow and wide concentric conductance fringes in the vicinity of the QR.
