Incompressible Biaxial Nematic Liquid Crystal Elastomers for Artificial Muscles

P.E. CLADIS\textsuperscript{1}, Advanced Liquid Crystal Tech., SIMON KRAUSE\textsuperscript{2}, Macromolecular Chemistry, YUSRIL YUSUF\textsuperscript{3}, Physics Department, S. HASHIMOTO\textsuperscript{4}, Department of Applied Quantum Physics and Nuclear Engineering, L. FEL\textsuperscript{5}, Department of Civil Engineering, HEINO FINKELMANN\textsuperscript{6}, Macromolecular Chemistry, SHOICHI KAI\textsuperscript{7}, Graduate School of Systems Life Sciences — Assuming only incompressibility, in the simplest complete theory for monodomain liquid crystalline elastomers as rectangular parallelepipeds, we find two biaxial nematic phases, $N_{2+}$ and $N_{2-}$ with a first order $N_{2+} - N_{2-}$ transition exhibiting spontaneous shape change. We identify $N_{2+}$ as icosahedral ($Y_h$) and $N_{2-}$, as simple orthorhombic ($D_{2h}$) nematics. Using standard orientational mechanics, we derive the stress-strain behavior before swelling to pin-point the recently discovered elastic strain limits for swelling with 5CB.
