Through the quasi one-dimensional lattice distortion (Peierls distortion) in In$_4$Se$_{3-x}$ bulk single crystals, we have achieved a high thermoelectric figure-of-merit $ZT$ of 1.48 at 705 K. From the Boltzman transport calculation, it was confirmed that the reported $ZT$ could be further increased if we could increase the chemical potential of the In$_4$Se$_{3-x}$ crystals. Here we report the significant increase of $ZT$ over a wide temperature range from 50 °C to 425 °C by chlorine doping in the In$_4$Se$_{3-x}$, which comes from the improvement of crystal quality and increase of chemical potential, resulting in the power factor enhancement and the thermal conductivity reduction.
