Capillary levelling as a probe of rheology in polymer thin films¹

JOSHUA D. MCGRAW, NICK M. JAGO, KARI DALNOKI-VERESS, Department of Physics and Astronomy and the Brockhouse Institute for Materials Research, McMaster University — While measuring the rheology of bulk polymer systems is routine, when the size of a system becomes comparable to the molecular size, flow properties are poorly understood and hard to measure. Here, we present the results of experiments that are easily performed and can probe the rheological properties of polymer films that are mere tens of nanometres in thickness. We prepare glassy bilayer polymer films with height profiles well approximated by a step function. Upon annealing above the glass transition, broadening of the height profiles due to gradients in the Laplace pressure is observed. By validating the technique as a probe of the rheology with a range of molecular weights, we will show that this robust technique can be used to investigate the effects of confinement and interfaces on the rheology of ultrathin polymer films.
