Role of disorder and doping in ferromagnetic double perovskites¹

ANAMITRA MUKHERJEE, OINAM NGANBA MEETEI, ONUR ERTEN, MOHIT RANDEIRA, NANDINI TRIVEDI, PATRICK WOODWARD², The Ohio State University — We use an effective classical spin model, which we have recently derived and validated, to examine the effect of disorder on the magnetic properties of double perovskites like $\text{Sr}_2\text{FeMoO}_6$ (SFMO). We compute the effects of excess Fe, excess Mo, and anti-site disorder on the magnetization $M(T)$ and the ferromagnetic transition temperature T_c , and show that our results are quantitatively consistent with available experiments. We then use these results to propose routes to increase the ferromagnetic T_c above that of pure SFMO (420K). We predict that, by adding excess Fe on Mo sites and compensating for the change in conduction electron density by La substitution on the Sr sites, we can raise T_c by as much as 40%, without substantially sacrificing the conduction electron polarization P at the chemical potential.
