Growths of InGaN Quantum Wells on GaN Micropiramids

RENBO SONG, LE ZHAO, GUANGYU LIU, JING ZHANG, NELSON TANSU, Lehigh University — Selective area epitaxy (SAE) of InGaN quantum wells on GaN micropiramids were grown by using metalorganic chemical vapor deposition (MOCVD). The pattern prepared for the SAE was fabricated by the deposition of 300 nm SiO₂ film on n-type GaN substrate by using plasma enhanced chemical vapor deposition (PECVD) and followed by photolithography. The grown micropiramide structures were characterized by scanning electron microscope (SEM) and photoluminescence (PL). Uniformly-distributed defect-free GaN micropiramids were observed by SEM. The growths of InGaN quantum wells were performed on the GaN micropiramids, and broadband luminescence were observed from the PL measurements applicable for white light-emitting diodes applications.
