

Abstract Submitted  
for the MAR12 Meeting of  
The American Physical Society

**Boson mode, Intermediate Phase, and glass molecular structure of heavy metal Oxides**<sup>1</sup> S. CHAKRABORTY, P. BOOLCHAND, U. of Cincinnati — We have synthesized bulk glasses of  $(\text{B}_2\text{O}_3)_5(\text{TeO}_2)_{95-x}(\text{V}_2\text{O}_5)_x$  ternary and examined their thermal and optical properties as a function of composition “x.” The enthalpy of relaxation at  $T_g$  shows a global minimum in the Vanadia concentration of  $24\% < x < 26.5\%$ , which we identify<sup>2</sup> as the intermediate phase (IP) with compositions at  $x < 24\%$  to be in stressed-rigid and those at  $x > 26.5\%$  in the flexible phase. Raman scattering reveals a rich lineshape including a Boson mode, whose scattering strength steadily decreases with increasing x, possibly due to bifurcation of weak ( $\text{Te-O}_{axial}$ ) and strong ( $\text{Te-O}_{equatorial}$ ) springs characteristic of  $\text{TeO}_2$  building blocks.<sup>3</sup> Vanadia alloying brings in isostatic building blocks, pyramidal  $\text{V}(\text{O}_{1/2})_3$  and quasi-tetrahedral  $\text{O}=\text{V}(\text{O}_{1/2})_3$  as suggested by present Raman scattering and recent  $^{51}\text{V}$  NMR data.<sup>4</sup> We describe the structure evolution of these glasses in terms of the Te-centered and V-centered local structures.
