Gegenwart, Georg-August-Universitat Gottingen, J. Kim, A.H. Said, D. Casa, T. Gog, M.H. Upton, Argonne National Laboratory, H.S. Kim, J. Yu, Seoul National University, V.M. Katukuri, L. Hozo, J.V.D. Brink, IFW Dresden, Y.J. Kim, University of Toronto — The electronic structure of the honeycomb lattice iridates \( \text{Na}_2\text{IrO}_3 \) and \( \text{Li}_2\text{IrO}_3 \) has been investigated using resonant inelastic x-ray scattering (RIXS). Crystal-field split \( d-d \) excitations are resolved in the high-resolution RIXS spectra. In particular, the splitting due to non-cubic crystal fields, derived from the splitting of \( j_{\text{eff}}=3/2 \) states, is much smaller than the typical spin-orbit energy scale in iridates, validating the applicability of \( j_{\text{eff}} \) physics in \( \text{A}_2\text{IrO}_3 \). We also find excitonic enhancement of the particle-hole excitation gap around 0.4 eV, indicating that the nearest-neighbor Coulomb interaction could be large. These findings suggest that both \( \text{Na}_2\text{IrO}_3 \) and \( \text{Li}_2\text{IrO}_3 \) can be described as spin-orbit Mott insulators, similar to the square lattice iridate \( \text{Sr}_2\text{IrO}_4 \).
