Evidence of f-electron localization at a heavy-fermion quantum critical point

FRANK STEGLICH, Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany

The prototypical heavy-fermion compound YbRh$_2$Si$_2$ exhibits a magnetic-field ($B$) induced antiferromagnetic quantum critical point (QCP) at $B_c$ ($\perp c$) $\approx$ 60 mT. As inferred from transport and thermodynamic measurements a quantum-critical energy scale, $k_B T^*(B)$, indicating a crossover of the Fermi surface, has been established for this system [1]. Upon extrapolating finite-temperature ($T$) data to $T = 0$, one concludes (i) a vanishing of $T^*(B)$ [2] and (ii) an abrupt drop in the (normal) Hall coefficient $R_H(B)$ [2, 3] at $B = B_c$, verifying the proposal of a Kondo destroying QCP [4,5]. The dynamical processes underlying this apparent break-up of the Kondo singlets have been explored [6-8] by studying the Lorenz ratio $L/L_0$ as a function of $T$ and $B$. Here, $L = \rho/w$ is the ratio of the electrical ($\rho$) and thermal ($w = L_0 T/\kappa$) resistivities, with $\kappa$ being the thermal conductivity and $L_0 = (\pi k_B)^2/3 e^2$ Sommerfeld’s constant. By properly taking care of bosonic (magnon/paramagnon) contributions to the heat current which exist at finite temperature only, extrapolation of the measured data to $T = 0$ yields a purely electronic Lorenz ratio $L/L_0 = 1$ at $B \neq B_c$. At $B = B_c$, we extrapolate $L/L_0 \approx 0.9$. Therefore, the Wiedemann Franz (WF) law holds at any value of the control parameter $B$, except for the field-induced QCP [6], as is also illustrated by a pronounced heating of the sample when measuring the low – $T$ electrical resistivity in the vicinity of the critical magnetic field [8]. This violation of the WF law is ascribed to scatterings of the electronic heat carriers from fermionic quantum-critical fluctuations, namely those of the Fermi surface.
