The American Physical Society

High pressure Raman spectroscopy of phase change materials

WEN-PIN HSIEH, Institute of Earth Sciences, Academia Sinica, PETER ZALDEN, Stanford Institute for Materials and Energy Sciences, SLAC, Menlo Park, CA, MATTHIAS WUTTIG, I. Physikalisches Institut (IA), RWTH Aachen University, 52056 Aachen, Germany, AARON LINDENBERG, Department of Materials Science and Engineering, Stanford University, Stanford, CA, WENDY MAO, Stanford Institute for Materials and Energy Sciences, SLAC and Dept. Geological & Environmental Sciences, Stanford Univ., Stanford, CA — We used high-pressure Raman spectroscopy to study the evolution of vibrational frequencies of the phase change materials (PCMs) $\text{Ge}_2\text{Sb}_2\text{Te}_5$, GeSb_2Te_4 , and SnSb_2Te_4 . We found that the critical pressure for triggering amorphization in the PCMs decreases with increasing vacancy concentration, demonstrating that the presence of vacancies, rather than differences in the atomic covalent radii, is crucial for pressure-induced amorphization in PCMs. Compared to the *as-deposited* amorphous phase, the *pressure-induced* amorphous phase has a similar vibrational spectrum, but requires much lower laser power to transform into the crystalline phase, suggesting different kinetics of crystallization, which may have implications for applications of PCMs in non-volatile data storage.
