Mott Glass Phase in the Disordered Quantum Spin Systems¹

DAO-XIN YAO, NVSEN MA, Sun Yat-sen University, ANDERS SANDVIK, Boston University — We use quantum Monte Carlo method to study the disordered $S = 1/2$ quantum spins on the square lattice with three different nearest neighbor interactions J_1 , J_2 and J_3 . Here J_1 represents weak bonds, and J_2 and J_3 correspond to stronger bonds which are randomly distributed on columnar rungs forming coupled 2-leg ladders. By tuning the average value of J_2 and J_3 , the system undergoes Néel-glass-paramagnetic quantum phase transition. A wide range of Mott glass phase has been found. We notice that its uniform susceptibility in the glass phase follows $\chi \sim \exp(-b/T^\alpha)$, where $0.5 < \alpha < 1$. Furthermore, this dimerized disordered quantum spin system shows the violation of Harris criterion.
