**A State Representation Approach for Atomistic Time-Dependent Transport Calculations in Molecular Junctions** TAMAR ZELOVICH, Tel Aviv University, Israel, LEEOR KRONIK, Weizmann Institute of Science, Israel, ODED HOD, Tel Aviv University, Israel — A new method for simulating electron dynamics in open quantum systems out of equilibrium, motivated by the intuitive and practical nature of the damped Liouville von-Neumann equation approach of Sánchez et al. [J. Chem Phys, 124, 214708 (2006)], is presented. The new approach is based on a transformation of the Hamiltonian matrix from an atomistic to a state representation of the molecular junction. This allows us to define the bias voltage across the system uniquely while maintaining a proper thermal distribution within the lead models. Furthermore, it allows us to investigate time-dependent effects in non-linear and multi-lead configurations. We investigate the degree of conservation of exact conditions such as the N-representability of the density matrix and suggest ways to remedy the violation of Pauli's exclusion principle. We believe that the new approach offers a practical and physically sound route for performing atomistic time-dependent transport calculations in realistic models of molecular electronics junctions.
