Pressure-induced superconductivity in *n*-type bismuth telluride

MARI EINAGA, TOMOKO KAGAYAMA, KATSUYA SHIMIZU, KYOKUGEN, Osaka University, AYAKO OHMURA, Center for Transdisciplinary Research, Niigata University, YUH YAMADA, Department of Physics, Niigata University — Stoichiometric bismuth telluride (Bi_2Te_3), which is a *p*-type semiconductor, has the rhombohedral structure with space group $R\bar{3}m$ at ambient condition. We have previously reported that pressure-induced superconductivity of stoichiometric *p*-type Bi_2Te_3 occurs in the high-pressure phases which appear above 8 GPa. However Bi_2Te_3 shows the variations of the carrier types, the carrier density, and the transport properties with the atomic composition. In this study, we performed the x-ray diffraction study and the electrical resistivity measurement of $\text{Bi}_{35}\text{Te}_{65}$ as the *n*-type Bi_2Te_3 sample under high pressure to investigate structural phase transition and pressure-induced superconductivity. At ambient condition, $\text{Bi}_{35}\text{Te}_{65}$ has also the $R\bar{3}m$ structure. It remains stable up to 8 GPa at room temperature. The superconducting transition is observed at 6 GPa below 2.9 K. The electrical resistivity at room temperature decreases rapidly at pressures from 7 to 8 GPa, indicating the occurrence of structural phase transition. It suggests that the superconducting transition at 6 GPa occurs at the ambient pressure phase with the $R\bar{3}m$ structure.
