Investigation of Thin Layered Cobalt Oxide Nano-Islands on Gold

MICHAL BAJDICH, SLAC - STANFORD, ALEX S. WALTON, JAKOB FESTER, iNANO, Aarhus University, MOHAMMAD A. ARMAN, JACEK OSIECKI, JAN KNUDSEN, Lund University, ALEKSANDRA VOJVODIC, SLAC - STANFORD, JEPPE V. LAURITSEN, iNANO, Aarhus University — Layered cobalt oxides have been shown to be highly active catalysts for the oxygen evolution reaction (OER), but the synergistic effect of contact with gold is yet to be fully understood. The synthesis of three distinct types of thin-layered cobalt oxide nano-islands supported on a single crystal gold (111) substrate is confirmed by combination of STM and XAS methods. In this work, we present DFT+U theoretical investigation of above nano-islands using several previously known structural models. Our calculations confirm stability of two low-oxygen pressure phases: (a) rock-salt Co-O bilayer and (b) wurtzite Co-O quadlayer and single high-oxygen pressure phase: (c) O-Co-O trilayer. The optimized geometries agree with STM structures and calculated oxidation states confirm the conversion from Co^{2+} to Co^{3+} found experimentally in XAS. The O-Co-O trilayer islands have the structure of a single layer of CoOOH proposed to be the true active phase for OER catalyst. For that reason, the effect of water on the Pourbaix stabilities of basal planes and edge sites is fully investigated. Lastly, we also present the corresponding OER theoretical overpotentials.
