XU, GENDA GU, PETER JOHNSON, Brookhaven Natl Lab, UWE BOVENSIEPEN, University of Duisburg-Essen — While in the last several years great strides have been made in the use of ultrafast optical excitation to induce non-equilibrium effects in the superconducting state of cuprate high T_c superconductors, less attention has been paid to what such pump-probe experiments might reveal about the equilibrium properties of these materials, particularly in their normal states. Recently we have investigated the non-equilibrium properties of the normal state of optimally doped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$ ($T_c = 91$ K) using time and angle resolved photoelectron spectroscopy (tr-ARPES). This effort revealed a pump-induced modification of the nodal mass renormalization at 70 meV as well as a longer-lived photodoping effect. Building on this work, we will present further findings related to the photodoping effect as it is manifested in the normal state of underdoped ($T_c = 50$ K) $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$.
