Unified Description of the Optical Phonon Modes in $N$-Layer MoTe$_2$

GUILLAUME FROEHLICHER, ETIENNE LORCHAT, FRANÇOIS FERNIQUE, IPCMS (CNRS - Université de Strasbourg), CHAITANYA JOSHI, ALEJANDRO MOLINA-SÁNCHEZ, LUDGER WIRTZ, University of Luxembourg, STÉPHANE BERCIAUD, IPCMS (CNRS - Université de Strasbourg) — $N$-layer transition metal dichalcogenides (denoted MX$_2$) provide a unique platform to investigate the evolution of the physical properties between the bulk (3D) and monolayer (quasi-2D) limits. Here, we present a unified analysis of the optical phonon modes in $N$-layer 2H-MX$_2$ [1]. The 2H-phase (or hexagonal phase) is the most common polytype for semiconducting MX$_2$ (such as MoS$_2$). Using Raman spectroscopy, we have measured the manifold of low-frequency (rigid layer), mid-frequency (involving intralayer displacement of the chalcogen atoms only), and high-frequency (involving intralayer displacements of all atoms) Raman-active modes in $N = 1$ to 12 layer 2H-molybdenum ditelluride (MoTe$_2$). For each monolayer mode, the $N$-dependent phonon frequencies give rise to fan diagrams that are quantitatively fit to a force constant model. This analysis allows us to deduce the frequencies of all the bulk (including silent) optical phonon modes. [1] G. Froehlicher, E. Lorchat, F. Fernique, C. Joshi, A. Monlina-Sánchez, L. Wirtz, and S. Berciaud, Unified Description of the Optical Phonon Modes in $N$-Layer MoTe$_2$, Nano Letters, 15 (10), pp 6481-6489 (2015)
