Neutron scattering study of the freezing of water near a cupric oxide surface\textsuperscript{1} J. TORRES, Z. N. BUCK, F. Z. ZHANG, T. CHEN, R. A. WINHOLTZ, H. KAISER, H. B. MA, H. TAUB, U. Mo., M. TYAGI, NIST — Oscillating heat pipes (OHP) offer promising two-phase heat transfer for a variety of applications, including cooling of electronic devices.\textsuperscript{2} Recently, it has been shown that a hydrophilic CuO coating on either the evaporator or condenser sections of a flat-plate OHP can significantly enhance its thermal performance.\textsuperscript{3} This finding has motivated us to assess the strength of the CuO/H\textsubscript{2}O interaction by investigating the freezing behavior of H\textsubscript{2}O in proximity to a CuO surface. Using the High-Flux Backscattering Spectrometer at NIST, we have measured the intensity of neutrons scattered elastically from a well-hydrated sample of CuO-coated Cu foils that mimic the oxide surfaces in a flat-plate OHP. We observe abrupt freezing of bulk-like H\textsubscript{2}O above the CuO surface at 270 K followed by continuous freezing of the interfacial H\textsubscript{2}O down to 265 K. This freezing behavior is qualitatively similar to that found for water near a zwitterionic single-supported bilayer lipid membrane.\textsuperscript{3} Further studies are planned to compare the diffusion coefficients of the interfacial water for the coated and uncoated OHPs.\textsuperscript{2} F.
