Nuclear magnetic resonance studies of bovine $\gamma B$-crystallin\(^1\)

GEORGE THURSTON, JEFFREY MILLS, LEA MICHEL, KAYLEE MATHEWS, JOHN ZANET, ANGEL PAYAN, KEITH VAN NOSTRAND, MICHAEL KOTLARYCHK, DAVID ROSS, Rochester Institute of Technology, CHRISTOPHER WAHLE, University of Findlay, JOHN HAMILTON, Rochester Institute of Technology — Anisotropy of shape and/or interactions play an important role in determining the properties of concentrated solutions of the eye lens protein, $\gamma B$-crystallin, including its liquid-liquid phase transition. We are studying $\gamma B$ anisotropic interactions with use of nuclear magnetic resonance (NMR) concentration- and temperature-dependent chemical shift perturbations (CSPs). We analyze two-dimensional heteronuclear spin quantum coherence (HSQC) spectra on backbone nitrogen and attached hydrogen nuclei for CSPs, up to 3 percent volume fraction. Cumulative distribution functions of the CSPs show a concentration and temperature-dependent spread. Many peaks that are highly shifted with either concentration or temperature are close (i) crystal intermolecular contacts (ii) locations of cataractogenic point mutations of a homologous human protein, human $\gamma D$-crystallin, and (iii) charged amino-acid residues. We also discuss the concentration- and temperature-dependence of NMR and quasielastic light scattering measurements of rotational and translational diffusion of $\gamma B$ crystallin in solution, affected by interprotein attractions.
