**Comparison the Photoluminescence and Magneto-transport
Techniques for Measuring 2D Electron Density in GaAs Quantum Wells¹**

LOREN PFEIFFER, DOBROMIR KAMBUROV, KIRK BALDWIN, KENNETH WEST, Princeton Univ — We compare photoluminescence (PL) and transport measurements as a measure of the electron density in clean, two-dimensional (2D) systems confined to GaAs quantum wells (QWs), grown via molecular beam epitaxy. We explore the PL shape evolution across a number of samples with different QWs and as-grown electron densities and study its correspondence with the density obtained in transport measurements. We also measure the 2D density in a top-gated quantum well sample in both PL and transport and find that they are in agreement to within a few percent. The PL measurements are sensitive to gate-induced 2D density changes as small as 10^9 electrons/cm². The spatial resolution of the PL 2D density measurement is $40\mu\text{m}$, which is already substantially better than is possible in spatial maps with magneto-transport. Our results establish that PL could be used as a reliable technique for non-invasive measurements of small density variations with high spatial resolution.
