Exploring AFQMC Calculations in Solids and Molecules

EDGAR JOSUE LANDINEZ BORDA, MIGUEL MORALES SILVA, Lawrence Livermore National Lab, BRENDA RUBENSTEIN COLLABORATION\textsuperscript{1}, JOHN GOMEZ COLLABORATION\textsuperscript{2} — The Auxiliary Field Quantum Monte Carlo (AFQMC) \cite{1} method has been outlined as a promising path to compute the electronic structure of strong correlated molecules and solids \cite{2},\cite{3}. We explore its capabilities in a broad range of solids and molecules with different types of chemical structure and bonding. In addition, we study the use of single and non-orthogonal multi-determinant wave functions \cite{4} in the calculation of the equation of state and atomization energies of the systems studied. Overall, we finding good agreement with experimental results.\textsuperscript{1}\cite{1}Shiwei Zhang, Henry Krakauer, Phys. Rev. Lett. 90. 136401 (2003). \textsuperscript{2}\cite{2} S.
