INS studies of Cobalt-Copper Catalyst for the Conversion of Syn-gas to Higher Oxygenates\textsuperscript{1} PHILLIP SPRUNGER, ZI WANG, MATTHEW PATTERSON, RICHARD KURTZ, JAMES SPIVEY, Louisiana State University — Cobalt-copper catalysts have been proposed for the synthesis of ethanol and higher oxygenates as a substitute of Rh and other high-cost noble metal catalysts. Two types of sites with atomic proximity are needed to form higher oxygenates: one to dissociate CO and a second to insert CO to the intermediates to form the CH\textsubscript{x}CO intermediate. Metallic cobalt is responsible for CO dissociation, while the nature of the site for CO insertion is still under study. We have utilized inelastic neutron scattering (INS) at the VISION beamline at SNS to probe intermediate surface species of this cobalt-copper catalyst. This unique technique allows for elucidation of mechanistic details of the CO insertion and subsequent CH\textsubscript{x}CO intermediate formation on the metal surfaces (Co\textsuperscript{0}, Co\textsubscript{2}C and/or Cu\textsuperscript{0}). In addition to XRD and EXAFS which show a unique surface Co-C carbide formation, a combination of both INS and computational modeling indicate that the active site for CH\textsubscript{x}CO intermediates.

\textsuperscript{1}Sponsored through the Louisiana Consortium for Neutron Scattering, DOE No. DE-SC0012432 with additional support from the LA BOR; also ORNLs Spallation Neutron Source (VISION Beamline), DOE-BES under Contract No. DE-AC0500OR22725.
