Failure of interdependent lattice networks in high dimensions

GABRIEL A CWILICH, STEVEN LOWINGER, SERGEY V BULDYREV, Department of Physics, Yeshiva University — We study the mutual percolation of two interdependent lattice networks for dimensions ranging from 2 to 7. We impose that the length of interdependency links connecting nodes in the two lattices be less than or equal to a certain value r . For each value of D and r , we find the mutual percolation threshold, $p_c[D, r]$, below which the system completely collapses through a cascade of failures following an initial destruction of a fraction $(1 - p)$ of the nodes selected at random in one of the lattices. We find that for each dimension $D < 6$ there is a value of $r = r_I > 1$ such that for $r \geq r_I$ the cascading failures occur as a discontinuous first order transition, while for $r < r_I$ the system undergoes a continuous second order transition, as in the classical percolation theory. In all dimensions, the interdependent lattices reach maximal vulnerability (maximal $p_c[D, r]$) at a distance $r = r_{max} > r_I$, before beginning to decrease as $r \rightarrow \infty$. The decrease becomes less significant as D increases and $p_c[D, r_{max}] - p_c[D, \infty]$ decreases exponentially with D .
