Observations of the Light Element Abundances and the Cosmological Baryon Density

DAVID TYTLER, UCSD

Three methods of measuring the mean cosmological density of baryons now agree within about 10 to 30%: the cosmic microwave background, the D/H ratio using Standard Big Bang Nucleosynthesis, and the Lyman-alpha absorption from neutral Hydrogen in the intergalactic medium. Using this baryon density, Standard Big Bang Nucleosynthesis predicts a factor 3 to 4 more ${}^7\text{Li}$ than is seen in halo stars. There are theoretical models that can allow halo stars to destroy ${}^7\text{Li}$, but these models are challenged by both the amount of destruction and the lack of variation amongst stars with different mass. We do not know whether these stars did destroy their ${}^7\text{Li}$. The baryon density also predicts systematically more ${}^4\text{He}$ than most measurements over the last 20 years. We review the measurements and modifications to BBN that might explain the tension between D, He and Li.
