

Abstract Submitted  
for the NWS15 Meeting of  
The American Physical Society

**Analysis of Tokamak Fusion Test Reactor (TFTR) Prototype of International Thermonuclear Experimental Reactor (ITER)**<sup>‡</sup> TIM HESTER, BOGDAN MAGLICH, DAN SCOTT, California Science & Engineering Corporation (CALSEC), CALSEC TEAM — TFTR *produced world record of 10 million watts of controlled fusion power* [1] (CFP-1994) was summarized in *Review* [1]. We present evidence [2] that: (1) TFTR input vs. output was 40 to 10 MW i.e. a power loss. (2) Review claims no experimental evidence for thermonuclear CFP production (only a calculation). (3) Ultra-high vacuum (UHV) required for  $\tau_E = 0.2$  s is  $10^{-9}$  torr. TFTR had no UHV pumps, resulting in  $10^{-3}$  torr, restricting  $\tau_E < 10^{-6}$  s,  $\ll$  thermalization time; 0.1 s., hence DT plasma did not occur. (4) Carbon ions were presented as D-T plasma. (5) Unknown neutron detector on unexplained neutron diamagnetic effect, measured “fusion neutron power” without particle energy identification, energy or coincidence. (6) 8 of 9 parameters claimed were inferred not measured. Quadratic test of TFTR data results [2] in zero thermonuclear fusion power contribution to 10 MW: SFP =  $(0 \pm 1)\%$ .
