Optogalvanic transients in a neon discharge plasma

NAVEED PIRACHA, John Carroll University, OH 44118, RYAN FEATHER, John Carroll University, TARIQ GILANI, Millersville University, PA 17551 — Time dependent optogalvanic signals induced by the 1s – 2p(4-6) laser excitations have been studied in the neon DC plasma. The decay rates related to all the four 1s levels have been derived by fitting the waveforms with a mathematical rate equation model. The temporal signatures of the two transitions namely 638 nm and 650 nm related to the 2p7 and 2p8 upper levels, respectively, have been found different from the rest of the transitions.
