Search for pair production of vector-like quarks that decay to a Z boson and a third-generation quark in trilepton final states in pp collisions at $\sqrt{s}=13$ TeV with the ATLAS detector

YOU ZHOU, ELLIOTT CHEU, University of Arizona — A search is outlined for the pair production of vector-like quarks that decay to a Z boson and a third-generation Standard Model quark. In the case of a charge $+2/3$ vector-like quark ($T$), the decay targeted is $T \rightarrow Zt$, while the decay targeted for a charge $-1/3$ vector-like quark ($B$) is $B \rightarrow Zb$. Selected events contain a high transverse momentum Z boson candidate reconstructed from a pair of oppositely charged same-flavor leptons (electrons or muons), and are analyzed in the final states defined by the presence of a third lepton. Hadronic jets, in particular those with properties consistent with the decay of a $b$-hadron, are also required to be present in selected events. The agreement between the simulated data and observed data is examined in various control regions defined by the absence of $b$-tagged jets and Z boson candidates with low transverse momentum. The lower limits are derived on the mass of vector-like $T$ and $B$ quarks considering only the statistical uncertainties under various branching ratio hypotheses.
