The American Physical Society

**Charge, from EM fields only.** R.L. COLLINS, U.T. Austin, retired — Purely electromagnetic particle (PEP) models of an electron have until now failed because they do not account for "charge". A model of the electron, built from EM fields only, has been found that generates a  $\mathbf{v}\mathbf{x}\mathbf{B}$  inverse square field that resembles the electric field  $\mathbf{E}$  we associate with charge. Does this model contain charge? Not really. Gauss' law says yes, but  $\text{div } \mathbf{v}\mathbf{x}\mathbf{B}$  finds no charge density. "Charge" is a mathematical fiction, useful but not fundamental. This model begins with a magnetic flux quantum configured as a magnetic dipole,  $\mu$ , spinning at  $\sqrt{3}$  times the Compton frequency  $\nu_C = mc^2/h$ . As it decays, energy is transferred to a toroidal displacement current. Oscillation between these configurations proceeds at  $\nu_C$ . The EM assembly carries angular momentum  $\mathbf{L}$ , spinning about  $\mu$ . Spinning  $\mathbf{B}$  leads to  $\mathbf{v}\mathbf{x}\mathbf{B}$ , an electric field that arises everywhere in space from spinning  $\mathbf{B}$  and not from some compact central "charge". Elastic Coulomb scattering must find the electron to be a point particle, without size even though the EM structure itself is huge.  $\mu$  undulates but does not reverse polarity. Faraday's static  $\mathbf{E}$  field does not exist in nature. The electric field about an electron is  $\mathbf{v}\mathbf{x}\mathbf{B}$ , inverse square and undulating at  $1.24 \times 10^{20}$  Hz.
