The American Physical Society

A PEP model of the electron. R.L. COLLINS, retired UT Austin — One of the more profound mysteries of physics is how nature ties together EM fields to form an electron. A way to do this is examined in this study. A bare magnetic dipole containing a flux quantum spins stably, and produces an inverse square $\mathbf{E} = -\mathbf{v}\mathbf{x}\mathbf{B}$ electric field similar to what one finds from “charge”. Gauss’ law finds charge in this model, though there be none. For stability, a current loop about the waist of the magnetic dipole is needed and we must go beyond the classical Maxwell’s equations to find it. A spinning \mathbf{E} field is equivalent to an electric displacement current. The sideways motion of the spinning \mathbf{E} (of constant magnitude) creates a little-recognized transverse electric displacement current about the waist. Transverse motion of \mathbf{E} supports the dipolar \mathbf{B} field, $\mathbf{B} = \mathbf{v}\mathbf{x}\mathbf{E}/c^2$. Beyond the very core of the magnetic dipole, each of these two velocities is essentially c and $\mathbf{v}\mathbf{x}\mathbf{E}/c^2 = \mathbf{v}\mathbf{x}(-\mathbf{v}\mathbf{x}\mathbf{B})/c^2 = \mathbf{B}$. The anisotropy of the $\mathbf{v}\mathbf{x}\mathbf{B}$ field is cured by precession about an inclined axis. Choosing a Bohr magneton for the magnetic dipole and assuming it spins at the Compton frequency, Gauss’ law finds $Q = e$. Charge is useful but not fundamental. With this, Maxwell’s equations can be written in terms of the \mathbf{E} and \mathbf{B} fields alone.
