Abstract for an Invited Paper
for the APR20 Meeting of
the American Physical Society

Why Galaxies Start Pickle-Shaped An Historical Introduction to Dark Matter and Galaxy Formation

JOEL PRIMACK, UCSC

Newtons laws explained why planetary orbits are elliptical, but not why the planetary orbits in the solar system are nearly circular, in the same plane, and in the same direction as the sun rotates. Laplace explained this as a consequence of angular momentum conservation as the sun and planets formed in a cooling and contracting protoplanetary gas cloud. For similar reasons, many astronomers once thought that galaxies would start as disks. But Hubble Space Telescope images of forming galaxies instead show that most of them are prolate that is, pickle-shaped. This turns out to be a consequence of most galaxies forming in prolate dark matter halos oriented along massive dark matter filaments. This talk will include background on the 2020 Lilienfeld Prize of the American Physical Society to Joel Primack for seminal contributions to our understanding of the formation of structure in the universe, and for communicating to the public the extraordinary progress in our understanding of cosmology.
