Hydrodynamic Predictions for O-O collisions at RHIC and LHC

NICHOLAS SUMMERFIELD¹, University of Houston, BING-NAN LU, Michigan State University, CHRISTOPHER PLUMBERG, University of Illinois at Urbana-Champaign, DEAN LEE, Michigan State University, JACQUELYN NORONHA-HOSTLER, MATTHEW SIEVERT, University of Illinois at Urbana-Champaign, ANTHONY TIMMINS, University of Houston — We present hydrodynamic predictions of anisotropic flow coefficients and average transverse momenta for O-O collisions at both $\sqrt{s_{NN}} = 200$ and 6.5 TeV energies. In particular, we investigate the effect of the relevant degrees of freedom in the initial nuclear state using the T_RENTo model. Alpha clustering is implemented using Lattice QCD calculations, and the corresponding hydrodynamic predictions are compared to modeling the nucleons independently using a Wood Saxon distribution with and without constituent quarks. We use VISHNN 2+1 hydrodynamics and the UrQMD hadronic afterburner to evolve the system, and the transport properties inputted result from a Bayesian analysis on p-Pb and Pb-Pb collision data at the LHC. We will also assess validity of hydrodynamics for O-O collisions by examining the Knudsen and Reynold values during the evolution.
