Heavy Photon Search Engineering Run HOLLY SZUMILA-VANCE,
Old Dominion University, HEAVY PHOTON SEARCH COLLABORATION —
The Heavy Photon Search (HPS) experiment at Jefferson Lab searches for a new
vector force carrier called the heavy photon. Heavy photons could kinetically mix
with Standard Model photons and be radiated off electron beams incident on a
fixed target. They may then decay to $e^+ e^-$ pairs promptly or after traveling a
short, resolvable distance, either of which can be detected experimentally. Heavy
photons have also been hypothesized as mediators between Standard Model and
dark matter particles. The HPS experiment took its first data in the engineering
run during the spring of 2015 using a 1 GeV electron beam and a 4 μm tungsten
target. The experiment utilized a silicon vertex tracker for momentum and vertex
reconstruction, together with an electromagnetic calorimeter to measure the energy
of electrons and positrons and to trigger events. This talk describes the detectors
and their performance during the engineering run.
