Progress and plans for the Free-Boundary PTRANSP project¹

L.P. KU, R. BUDNY, S. JARDIN, C. KESSEL, D. MCCUNE, Princeton University, Plasma Physics Laboratory, H. ST. JOHN, General Atomics Corporation, D. GROTE, L. LODESTRO, T. ROGNLIEN², G. BATEMAN, A. KRITZ, Lehigh University — We describe progress on a two-year multi-institutional project to develop a Free-Boundary PTRANSP capability. A prototype PTRANSP client-server configuration has now been developed and successfully tested using ITER simulation data. In this configuration, TRANSP acts as a server, computing RF, neutral beam and fusion product heating and current drive at the request of the free boundary predictive code client. The TRANSP server simultaneously carries out an analysis of the predictive code results, using the same methods as currently employed for tokamak experimental data analysis. A standard TRANSP archive output is produced. Equilibrium and profiles are communicated using the NTCC XPLASMA module; synchronization is done by ascii signaling files. The longer range vision is for an integrated predictive transport code that is fully coupled to the UEDGE edge transport code and to a number of existing MHD equilibrium and stability codes and transport models.
