Impurity Flow Measurements in DIII-D using Coherence Imaging Spectroscopy¹ S.L. ALLEN, E.T. MEIER, T.R. WEBER, D.N. HILL, W.H. MEYER, G.D. PORTER, Lawrence Livermore National Laboratory, J. HOWARD, The Australian National University — Imaging interferometers have been used to measure the 2-D distribution of the Doppler shift of impurity emission in both the lower and upper DIII-D divertors. The interferometer design has been simplified to a single birefringent plate between two polarizers, and improved calibration techniques have been implemented, including temperature stabilization. Measurements of other impurity species such as CII have been added. An image-intensified camera in the upper divertor has enabled measurement of the flows in the crown of the plasma during lower single-null divertor operation. In general, flows are in opposite directions on the inner and outer scrape-off layers in the divertor, as expected from the magnetic geometry. Initial results from a wide view periscope of the whole plasma cross section will also be presented.
